

MySQL RDBMS

Trainer: Mr. Nilesh Ghule

- Transaction is set of DML queries executed as a single unit.
- Transaction examples
 - accounts table [id, type, balance]
- - ✓ UPDATE accounts SET balance=balance+1000 WHERE id = 2; ∠
- RDBMS transaction have ACID properties.
 - Atomicity
 - All queries are executed as a single unit. If any query is failed, other queries are discarded.
 - Consistency
 - When transaction is completed, all clients see the same data.
 - Isolation
 - Multiple transactions (by same or multiple clients) are processed concurrently.
 - Durable
 - When transaction is completed, all data is saved on disk.

- Transaction management
 - START TRANSACTION;
 - · ... 三
 - COMMIT WORK;
 - START TRANSACTION;
 - ... =
 - ROLLBACK WORK;
- In MySQL autocommit variable is by default 1. So each DML command is autocommitted into database.

work keyword optional.

- SELECT @@autocommit;
- Changing autocommit to 0, will create new transaction immediately after current transaction is completed. This setting can be made permanent in config file.
 - SET autocommit=0;

- Save-point is state of database tables (data) at the moment (within a transaction).
- It is advised to create save-points at end of each logical section of work.
- Database user may choose to rollback to any of the save-point.
- Transaction management with Save-points
 - START TRANSACTION;
 - · ... =
 - SAVEPOINT sa1;
 - 💢 =
 - SAVEPOINT sa2; ✓
 - > =
 - ROLLBACK TO sa1;
 - ... =
 - COMMIT; // or ROLLBACK
- Commit always commit the whole transaction.
- ROLLBACK or COMMIT clears all save-points.

```
start transaction;
donle;
```

- Transaction is set of DML statements.
- If any DDL statement is executed, current transaction is automatically committed.
- Any power failure, system or network failure automatically rollback current state.
- Transactions are isolated from each other and are consistent.

Row locking

- When an user update or delete a row (within a transaction), that row is locked and becomes read-only for other users.
- The other users see old row values, until transaction is committed by first user.
- If other users try to modify or delete such locked row, their transaction processing is blocked until row is unlocked.
- Other users can INSERT into that table. Also they can UPDATE or DELETE other rows.
- The locks are automatically released when COMMIT/ROLLBACK is done by the user.
- This whole process is done automatically in MySQL. It is called as "OPTIMISTIC LOCKING".

Row locking

- Manually locking the row in advanced before issuing UPDATE or DELETE is known as "PESSIMISTIC LOCKING".
- This is done by appending FOR UPDATE to the SELECT query.
- It will lock all selected rows, until transaction is committed or rollbacked.
- If these rows are already locked by another users, the SELECT operation is blocked until rows lock is released.
- By default MySQL does table locking.
 Row locking is possible only when table is indexed on the column.

Thank you!
